

THE ART OF SHADOWS

Here in the tropics, it's the shade not the stove that refreshes and brings people together.

- Bruno Stagno, a Costa Rican architect, on tropical architecture

Stagno captures a profound truth about tropical living: shade is not merely a luxury, it is a social and environmental necessity.

BUILT FOR
SHADE,
DESIGNED FOR
COMFORT

WHAT IS MUTUAL SHADING?

Mutual shading is a phenomenon in urban design and architecture where buildings cast shadows on each other, reducing the amount of direct solar radiation that reaches adjacent structures. This inter-building effect can significantly influence energy consumption—particularly cooling loads in tropical climates—by minimizing solar heat gain on building facades.

Nila's Cool Embrace

At Nila, mutual shading is an act of care. We understand that in a climate where heat is relentless, a well-placed shadow is a gift. Our buildings are not isolated monoliths. They are designed as a community that works together to keep electricity bills low and residents comfortable.

HOW NILA EMBRACES MUTUAL SHADING

01

STRATEGIC BUILDING ORIENTATION

Buildings are positioned to maximize shading during peak sun hours, with careful consideration of solar angles throughout the year, particularly the harsh summer sun.

02

BUILDING FORM & MASSING

The massing and profile of Nila's buildings are designed to cast shadows on adjacent structures, creating a self-shading community.

03

OPTIMAL BUILDING SPACING

Spacing between buildings is calibrated to allow for cooling airflow while still providing effective shade, balancing ventilation and protection.

04

FAÇADE DESIGN

Façades are built with shading features, extending protection even when adjacent buildings are not casting shadows.
